Chapter 7
Single-Dimensional Arrays
Arrays

Array is a data structure that represents a collection of same-types data elements.

A single-dimensional array is one that stores data elements in one row.

Strings are arrays.

String Name = "John Smith";

String courseNumber;
courseNumber = new String ("CS 1301");
Declaring Array Variables

datatype[] arrayRefVar;

Example:

    double[] myList;    //vs. double myList;
    int[] yourList;
    boolean[] herList;
    char[] hisList;

datatype arrayRefVar[];  //This style is allowed, but not preferred

Example:

    double myList[];
Creating Arrays

This is to **allocate memory space** for the array.

```
arrayRefVar = new datatype[arraySize];
```

Example:

```
myList = new double[10];
yourList = new int[100];
herList = new boolean[20];
hisList = new char[500];
```

**myList[0]** references the first element in the array.

**myList[9]** references the last element in the array.

**In one step you can declare and create:**

```
double[] myList = new double[10];
```
The Length of an Array

Once an array is created, **its size is fixed**. It cannot be changed. You can find its size using

```java
arrayRefVar.length; (not length() as with strings)
```

For example,

```java
int length = myList.length;    // returns 10
int length = yourList.length;  // returns 100;
int length = herList.length;   // returns 20;
int length = hisList.length;   // returns 500;
```
```java
double[] myList = new double[10];
```

<table>
<thead>
<tr>
<th>Array reference variable</th>
<th>Array element at index 5</th>
<th>Element value</th>
</tr>
</thead>
<tbody>
<tr>
<td>myList</td>
<td>myList[0]</td>
<td>5.6</td>
</tr>
<tr>
<td></td>
<td>myList[1]</td>
<td>4.5</td>
</tr>
<tr>
<td></td>
<td>myList[2]</td>
<td>3.3</td>
</tr>
<tr>
<td></td>
<td>myList[3]</td>
<td>13.2</td>
</tr>
<tr>
<td></td>
<td>myList[4]</td>
<td>4.2</td>
</tr>
<tr>
<td></td>
<td>myList[5]</td>
<td>34.33</td>
</tr>
<tr>
<td></td>
<td>myList[6]</td>
<td>34.7</td>
</tr>
<tr>
<td></td>
<td>myList[7]</td>
<td>45.45</td>
</tr>
<tr>
<td></td>
<td>myList[8]</td>
<td>99.993</td>
</tr>
<tr>
<td></td>
<td>myList[9]</td>
<td>111.23</td>
</tr>
</tbody>
</table>
When an array is created, its elements are assigned the default value of

0 for the numeric primitive types (byte, short, int, long)
0.0 for the numeric primitive data types (float, double)
'\u0000' for char types (Null value)
false for boolean type.
Indexed Variables

The array elements are accessed through the index.

The array indices start from 0 to `arrayRefVar.length-1`.

Example:

```java
double[] myList = new double[5];
Array myList holds five double values
The indices are 0 to 4.
```

Each element in the array is represented using the following syntax, known as an `indexed variable`:

`arrayRefVar[index];`

```java
myList[0] = 25.7; // value in first element
double price = myList[3];
```
Using Indexed Variables

After an array is created, an indexed variable can be used in the same way as a regular variable is used.

Example:
The following code adds the values in the first and second positions in array `myList` and stores the result in the third position.

```
myList[2] = myList[0] + myList[1];
```

Example:
The following code prints out the content of array `myList`.

```
for (int i = 0; i <= myList.length-1; i++)
    System.out.println("Value in position "+ i +
                     " = " + myList[i]);
```
Array Initialization

Declaring, creating, initializing in one step:

```java
double[] myList = {1.9, 2.9, 3.4, 3.5};
int[] numberGrades = {70, 65, 87, 93, 90};
char[] letterGrades = {'C', 'D', 'B', 'A', 'A'};
boolean[] myFlags = {true, false, true, false};
```

This shorthand notation is equivalent to the following statements:

```java
double[] myList = new double[4];
myList[0] = 1.9;
myList[1] = 2.9;
myList[2] = 3.4;
myList[3] = 3.5;
```

Be Careful! This code gives an error. It must be in one statement.

```java
int[] numberGrades;
numberGrades = {70, 65, 87, 93, 90};
```
public class Test {
    public static void main(String[] args) {
        int[] values = new int[5];
        for (int i = 1; i < 5; i++) {
            values[i] = i + values[i-1];
        }
        values[0] = values[1] + values[4];
    }
}
public class Test {
    public static void main(String[] args) {
        int[] values = new int[5];
        for (int i = 1; i < 5; i++) {
            values[i] = i + values[i-1];
        }
        values[0] = values[1] + values[4];
    }
}
public class Test {
    public static void main(String[] args) {
        int[] values = new int[5];
        for (int i = 1; i < 5; i++) {
            values[i] = i + values[i-1];
        }
        values[0] = values[1] + values[4];
    }
}
public class Test {
    public static void main(String[] args) {
        int[] values = new int[5];
        for (int i = 1; i < 5; i++) {
            values[i] = i + values[i-1];
        }
        values[0] = values[1] + values[4];
    }
}
public class Test {
    public static void main(String[] args) {
        int[] values = new int[5];
        for (int i = 1; i < 5; i++) {
            values[i] = i + values[i-1];
        }
        values[0] = values[1] + values[4];
    }
}
public class Test {
    public static void main(String[] args) {
        int[] values = new int[5];
        for (int i = 1; i < 5; i++) {
            values[i] = i + values[i-1];
        }
        values[0] = values[1] + values[4];
    }
}
public class Test {
    public static void main(String[] args) {
        int[] values = new int[5];
        for (int i = 1; i < 5; i++) {
            values[i] = i + values[i-1];
        }
        values[0] = values[1] + values[4];
    }
}
public class Test {
    public static void main(String[] args) {
        int[] values = new int[5];
        for (int i = 1; i < 5; i++) {
            values[i] = i + values[i-1];
        }
        values[0] = values[1] + values[4];
    }
}
public class Test {
    public static void main(String[] args) {
        int[] values = new int[5];
        for (int i = 1; i < 5; i++) {
            values[i] = i + values[i-1];
        }
        values[0] = values[1] + values[4];
    }
}
public class Test {
    public static void main(String[] args) {
        int[] values = new int[5];
        for (int i = 1; i < 5; i++) {
            values[i] = i + values[i-1];
        }
        values[0] = values[1] + values[4];
    }
}

After this line, values[3] becomes 6 (3 + 3)
public class Test {
    public static void main(String[] args) {
        int[] values = new int[5];
        for (int i = 1; i < 5; i++) {
            values[i] = i + values[i-1];
        }
        values[0] = values[1] + values[4];
    }
}
public class Test {
    public static void main(String[] args) {
        int[] values = new int[5];
        for (int i = 1; i < 5; i++) {
            values[i] = i + values[i-1];
        }
        values[0] = values[1] + values[4];
    }
}
public class Test {
    public static void main(String[] args) {
        int[] values = new int[5];
        for (int i = 1; i < 5; i++) {
            values[i] = i + values[i-1];
        }
        values[0] = values[1] + values[4];
    }
}

After this, values[4] becomes 10 (4 + 6)
public class Test {
    public static void main(String[] args) {
        int[] values = new int[5];
        for (int i = 1; i < 5; i++) {
            values[i] = i + values[i-1];
        }
        values[0] = values[1] + values[4];
    }
}
public class Test {
    public static void main(String[] args) {
        int[] values = new int[5];
        for (int i = 1; i < 5; i++) {
            values[i] = i + values[i-1];
        }
        values[0] = values[1] + values[4];
    }
}

i ( =5) < 5 is false. Exit the loop

After the fourth iteration

<td>10</td>
</tr>
</tbody>
</table>
public class Test {
    public static void main(String[] args) {
        int[] values = new int[5];
        for (int i = 1; i < 5; i++) {
            values[i] = i + values[i-1];
        }
        values[0] = values[1] + values[4];
    }
}
Processing Arrays

Some common examples:

1. (Initializing arrays with input values)
2. (Initializing arrays with random values)
3. (Printing arrays)
4. (Summing all elements)
5. (Finding the largest element)
6. (Finding the smallest index of the largest element)
7. (Random shuffling)
8. (Shifting elements)
Initializing arrays with input values

```java
... //Some code

double[] myList = new double[5];

java.util.Scanner input = new java.util.Scanner(System.in);

System.out.print("Enter " + myList.length + " double values: ");

for (int i = 0; i < myList.length; i++)
    myList[i] = input.nextDouble();

... //other code
```
Initializing arrays with random values

... //Some code

double[] myList = new double[5];

... //initialize the array

for (int i = 0; i < myList.length; i++)
    myList[i] = Math.random() * 100;  //double type

... //other code
... //Some code

double[] myList = new double[5];

... //initialize the array

for (int i = 0; i < myList.length; i++)
    System.out.print(myList[i] + " ");

... //other code
Summing all elements

... //Some code

double total = 0;

double[] myList = new double[5];

... //initialize the array

for (int i = 0; i < myList.length; i++)
    total = total + myList[i];

... //other code
Finding the largest element

... //Some code

double[] myList = new double[5];

double max = myList[0];

for (int i = 1; i < myList.length; i++)
{
    if (myList[i] > max)
        max = myList[i];
}

... //other code
Random shuffling

```java
for (int i = 0; i < myList.length; i++) {
    // Generate an index j randomly
    int index = (int)(Math.random() * myList.length);

    // Swap myList[i] with myList[j]
    double temp = myList[i];
    myList[i] = myList[index];
    myList[index] = temp;
}
```
double temp = myList[0]; // Retain the first element

// Shift elements left
for (int i = 1; i < myList.length; i++)
{
    myList[i - 1] = myList[i];
}

// Move the first element to fill in the last position
myList[myList.length - 1] = temp;
JDK 1.5 introduced a new for loop that enables you to traverse the complete array sequentially without using an index variable. For example, the following code displays all elements in the array myList:

```java
int[] myList = new int[5];
...
for (int value: myList)
    System.out.println(value);
```

In general, the syntax is

```java
For (elementType value: arrayRefVar) {
    // Process the value
}
```

You still have to use an index variable if you wish to traverse the array in a different order or change the elements in the array.
Copying Arrays

For object references, an assignment statement copies the memory address NOT the array content:

Before:

name1

"Steve Jobs"

name2

"Steve Wozniak"

name2 = name1;

After:

name1

"Steve Jobs"

name2
Copying Arrays

Use a loop:

```java
int[] sourceArray = {2, 3, 1, 5, 10};
int[] targetArray = new int[sourceArray.length];
for (int i = 0; i < sourceArray.length; i++)
    targetArray[i] = sourceArray[i];
```
The `arraycopy` Utility

`arraycopy(sourceArray, src_pos, targetArray, tar_pos, length);`

Example:

`System.arraycopy(sourceArray, 0, targetArray, 0, sourceArray.length);`

This will copy every element in `sourceArray` to `targetArray`. Must create `targetArray` first.

`System.arraycopy(sourceArray, 10, targetArray, 10, length);`

This will copy every element in `sourceArray` to `targetArray` starting at position 10. Must create `targetArray` first.
Passing Arrays to Methods

```java
public static void printArray(int[] array) {
    for (int i = 0; i < array.length; i++) {
        System.out.print(array[i] + " ");
    }
}
```

Invoke the method:

```java
int[] list = {3, 1, 2, 6, 4, 2};
printArray(list);
```

Invoke the method again:

```java
printArray(new int[]{3, 1, 2, 6, 4, 2});
```

Anonymous (nameless) array
Anonymous Array

The statement

\[
\text{printArray}(\text{new int[]}\{3, 1, 2, 6, 4, 2\});
\]

creates un-named array and pass it to method printArray().

There is no explicit reference variable for the this array. Such array is called an \textit{anonymous array}. 
Pass By Value - Revisited

Java uses *pass by value* to pass arguments to a method. There are important differences between passing a value of variables of primitive data types and passing arrays.

- For a parameter of a *primitive type* value, the actual value is passed. Changing the value of the local parameter inside the method *does not affect* the value of the variable outside the method.

- For a parameter of an *array type*, the value of the parameter contains a reference to an array; *this reference is passed to the method*. Any changes to the array that occur inside the method body *will affect* the original array that was passed as the argument.
public class Test {
    public static void main(String[] args) {
        int x = 1; // x represents an int value
        int[] y = new int[10]; // y is an array of int values
        myMethod(x, y); // Invoke m with arguments x and y
        System.out.println("x is " + x);
        System.out.println("y[0] is " + y[0]);
    }
    
    public static void myMethod(int number, int[] numbers) {
        number = 1001; // Assign a new value to number, locally
        numbers[0] = 5555; // Assign a new value to numbers[0]
    }
}
When invoking `myMethod(x, y)`, the values of `x` and `y` are passed to `number` and `numbers`. Since `y` contains the reference value to the array (memory address), `numbers` now contains the same reference value to the same array.
Call (Run-Time) Stack

Space required for the main method
int[] y: reference
int x: 1

Space required for method myMethod
int[] numbers: reference
int number: 1001

The arrays are stored in a heap.

Array of ten int values is stored here
Call (Run-Time) Stack

Space required for the main method:
- int[] y: reference
- int x: 1

Heap:
- 5555
- 0
- 0

The arrays are stored in a heap.
Java allows a method to take variables number of parameters of the same type. The parameter list is treated as an array.

```java
public class VarArgsDemo {
    public static void main (String[] args) {
        printMax(50, 29, 19, 2, 98, 16);
        printMax(150, 300, 275);
        printMax(new int[] {1,2,3,4,5,6});
    }

    public static void printMax(int... numbers) {
        if (numbers.length == 0) {
            System.out.println("No arguments passed! ");
            return; // to exit the method, not to return a value
        }
        int result = numbers[0];
        for (int i=1; i<numbers.length; i++)
            if (numbers[i] > result)
                result = numbers[i];
        System.out.println("The max value is " + result);
    }
}
```
Searching is the process of looking for a specific element in an array. The element may be found or may not.

How? Two commonly used methods are:
- **linear search:** search all elements in sequence from first to last.
- **binary search:** search an ordered array taking into consideration one-half of the array in each stop.
Linear Search

The linear search approach compares the key element, \texttt{key} or \texttt{target}, \textit{sequentially} with each element in the array \texttt{list}. The method continues to do so until the key matches an element in the list or the list is exhausted without a match being found. If a match is made, the linear search returns the index of the element in the array that matches the key. If no match is found, the search returns \texttt{-1}.

```
public class LinearSearch {
    /** The method for finding a key in the list */
    public static int linearSearch(int[] list, int key) {
        for (int i = 0; i < list.length; i++)       
            if (key == list[i])
                return i;
        return -1;
    }
}
```

list

key  Compare key with list[i] for i = 0, 1, …

</tbody>
</table>
Binary Search

For binary search to work, the elements in the array must already be ordered. Without loss of generality, assume that the array is in ascending order.

\[ \text{e.g.: } 2 4 7 10 11 45 50 59 60 66 69 70 79 \]

The binary search first compares the key with the element in the middle of the array.

- If the key is less than the middle element, you only need to search the key in the first half of the array.
- If the key is equal to the middle element, the search ends with a match.
- If the key is greater than the middle element, you only need to search the key in the second half of the array.
Binary Search

Key | List
---|---
8   | 1 2 3 4 6 7 8 9
8   | 1 2 3 4 6 7 8 9
8   | 1 2 3 4 6 7 9 8

- 2  4  7  10  11  45  50  59  60  66  69  70  79

**Key < 66**

- 59  60  66  69  70  79

**Key < 59**

- 59  60
/** Use binary search to find the key in the list */
public static int binarySearch(int[] list, int key) {
    int low = 0;
    int high = list.length - 1;

    while (high >= low) {
        int mid = (low + high) / 2;  // middle element
        if (key < list[mid])
            high = mid - 1;
        else if (key == list[mid])
            return mid;  // target is found
        else
            low = mid + 1;
    }
    return -1 - low;  // target not found!
}
Since binary search is frequently used in programming, Java provides several overloaded binarySearch methods for searching a key in an array of int, double, char, short, long, and float in the java.util.Arrays class. For example:

```java
import java.util.*;
int[] list = {2,4,7,10,11,45,50,59,60,66,69,70,79};
System.out.println("Index of value 11 is " + Arrays.binarySearch(list, 11));

char[] chars = {'a','c','g','x','y','z'};
System.out.println("Index of letter t is " + Arrays.binarySearch(chars, 't'));
```

*Note: This call returns –4 (insertion point is 3, so return is -3-1)*

For the binarySearch method to work, the array must be pre-sorted in increasing order. See section 7.12, page 272, for other methods. (Arrays.sort, Arrays.equals, Arrays.fill, Arrays.toString)
Sorting, like searching, is also a common task in computer programming. Many different algorithms have been developed for sorting.

This section introduces algorithm *selection sort*. 
Selection Sort

Selection sort finds the smallest number in the list and places it first. It then finds the smallest number remaining and places it second, and so on until the list contains only a single number.

```
Select 1 (the smallest) and swap it with 2 (the first) in the list.

2 9 5 4 8 1 6

The number 1 is now in the correct position and thus no longer needs to be considered.

1 9 5 4 8 2 6

Select 2 (the smallest) and swap it with 9 (the first) in the remaining list.

1 2 5 4 8 9 6

The number 2 is now in the correct position and thus no longer needs to be considered.

1 2 5 4 8 9 6

Select 4 (the smallest) and swap it with 5 (the first) in the remaining list.

1 2 4 5 8 9 6

The number 4 is now in the correct position and thus no longer needs to be considered.

1 2 4 5 8 9 6

5 is the smallest and in the right position. No swap is necessary.

1 2 4 5 8 9 6

Select 6 (the smallest) and swap it with 8 (the first) in the remaining list.

1 2 4 5 8 9 6

The number 5 is now in the correct position and thus no longer needs to be considered.

1 2 4 5 8 9 6

Select 8 (the smallest) and swap it with 9 (the first) in the remaining list.

1 2 4 5 6 9 8

The number 6 is now in the correct position and thus no longer needs to be considered.

1 2 4 5 6 9 8

Since there is only one element remaining in the list, the sort is completed.

1 2 4 5 6 8 9
```
The Algorithm

```java
for (int i = 0; i < list.length; i++) {
    // select the smallest element in list[i..listSize-1];
    // swap the smallest with list[i], if necessary;
    // list[i] is in its correct position.
    // The next iteration apply on list[i..listSize-1]
}
```

--

```
```

...
/** The method for sorting the numbers */

public static void selectionSort(double[] list) {
    for (int i = 0; i < list.length; i++) {
        // Find the minimum in the list[i..list.length-1]
        double currentMin = list[i];
        int currentMinIndex = i;
        for (int j = i + 1; j < list.length; j++) {
            if (currentMin > list[j]) {
                currentMin = list[j];
                currentMinIndex = j;
            }
        }
        // Swap list[i] with list[currentMinIndex] if necessary;
        if (currentMinIndex != i) {
            list[currentMinIndex] = list[i];
            list[i] = currentMin;
        }
    }
}
Arrays.sort Method

Since sorting is frequently used in programming, Java provides several overloaded sort methods for sorting an array of int, double, char, short, long, and float in the java.util.Arrays class. For example, the following code sorts an array of numbers and an array of characters.

```java
import java.util.*;

double[] numbers = {6.0, 4.4, 1.9, 2.9, 3.4, 3.5};
Arrays.sort(numbers);

char[] chars = {'a', 'A', '4', 'F', 'D', 'P'};
Arrays.sort(chars);
```
Arrays.toString(list) Method

Method Arrays.toString(list) method can be used to return a string representation for the list.

```java
import java.util.*;
char[] chars = {'a', 'A', '4', 'F', 'D', 'P'};
Arrays.sort(chars);  //sort the list
//print the list
for (int i = 0; i < chars.length; i++)
    System.out.print(chars[i]+ " ");

System.out.println(); //convert array to string
String myString = Arrays.toString(chars); System.out.println (myString);
```

**Output:**
```
4 A D F P a
[4, A, D, F, P, a]
```
You can call a regular method by passing actual parameters. Can you pass arguments to `main`? Of course, yes. For example, the main method in class `B` is invoked by a method in `A`, as shown below:

```java
public class A {
    public static void main(String[] args) {
        String[] strings = {"New York", "Boston", "Atlanta"};
        B.main(strings);
    }
}

class B {
    public static void main(String[] args) {
        for (int i = 0; i < args.length; i++)
            System.out.println(args[i]);
    }
}
```
